## 10707 Deep Learning: Spring 2021

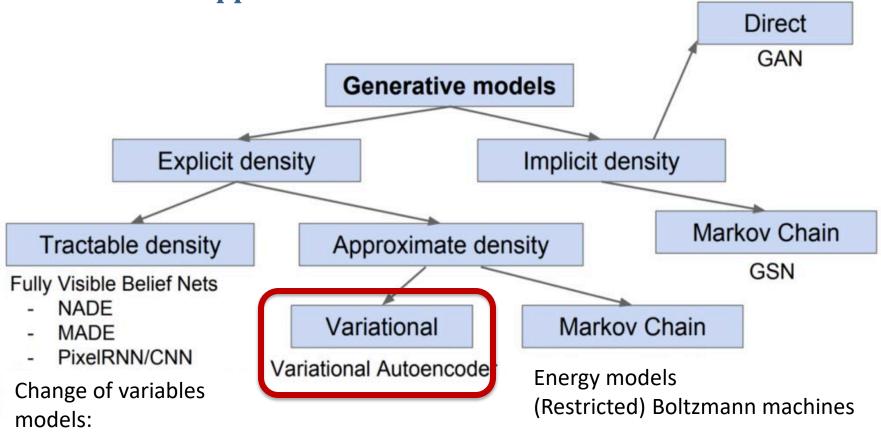

Andrej Risteski

Machine Learning Department

### **Lecture 11+12:**

Variational methods, directed latent-variable models

The distribution  $p_{\theta}(x)$  does not have a tractable form, but we can write down a variational approximation thereof.

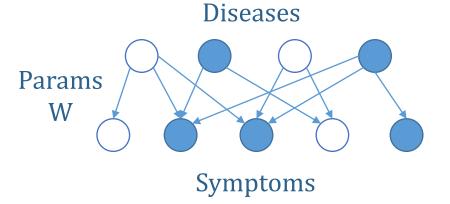

- (Nonlinear) ICA
- Normalizing flows

## Part I: Bayesian networks

Directed Graphs are useful for expressing causal relationships between random variables.

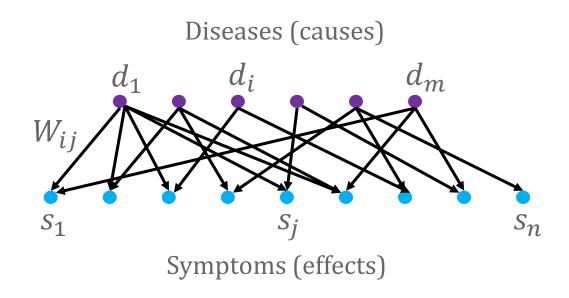

Your **symptoms**: fever + loss of taste.

Probability that you have covid?

Bayesian network succinctly describes Pr[symptom| diseases]

### Noisy-OR networks

Secondary Each  $d_i$  is on **independently** with prob.  $\rho$ Secondary When  $d_i$  is on, it **activates**  $s_j$  with probability  $1 - \exp(-W_{ij})$ .
Secondary  $s_j$  is **on** if one of  $d_i$ 's **activates**  $s_j$ 

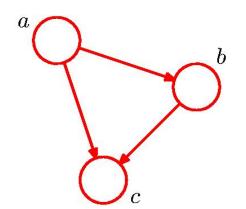

Directed Graphs are useful for expressing causal relationships between random variables.

"Deriving" Bayesian Networks as restrictions of arbitrary distributions:

An **arbitrary** joint distribution p(a,b,c) over three random variables a,b, and c can be written as

$$p(a,b,c) = p(c|a,b)p(a,b) = p(c|a,b)p(b|a)p(a)$$

Associate a graph with the decomposition:

- Node for each of the random variables.
- Add **directed** links to the graph from the nodes corresponding to the vars on which the distribution is conditioned.

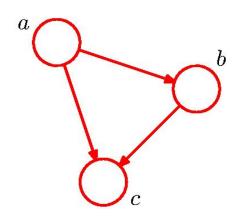

Directed Graphs are useful for expressing causal relationships between random variables.

"Deriving" Bayesian Networks as restrictions of arbitrary distributions:

An **arbitrary** joint distribution p(a,b,c) over three random variables a,b, and c can be written as

$$p(a,b,c) = p(c|a,b)p(a,b) = p(c|a,b)p(b|a)p(a)$$

Associate a graph with the decomposition:

Different ordering => different graphical representation.

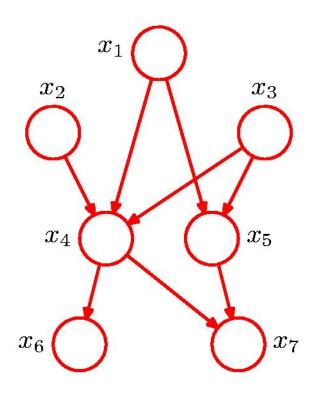

Joint distribution over K variables factorizes:

$$p(x_1,\ldots,x_K) = p(x_K|x_1,\ldots,x_{K-1})\ldots p(x_2|x_1)p(x_1)$$

Corresponding undirected graph is fully connected:

(as each lower-numbered node points to each higher-numbered node)

A graph that is **not** fully connected conveys information about the conditional independence structure of the distribution it encodes.

E.g. consider the graph on the left.

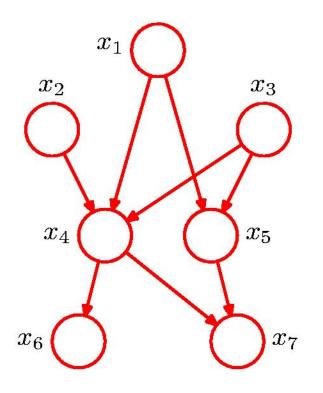

It encodes distributions over  $x_1,...,x_7$  that can be written as the product:

$$p(x_1, \dots, x_7) = p(x_1)p(x_2)p(x_3)p(x_4|x_1, x_2, x_3)$$
$$p(x_5|x_1, x_3)p(x_6|x_4)p(x_7|x_4, x_5)$$

Note the change from the previous slide: e.g.  $x_5$  is **not** conditioned on all of  $x_{1,} x_{2,} x_{3,} x_4$  but only on  $x_{1,} x_{3,}$ 

## The general case: factorization

The joint distribution defined by the graph is given by the product of a conditional distribution for each node conditioned on its parents:

$$p(\mathbf{x}) = \prod_{k=1}^{K} p(x_k | \mathbf{pa}_k)$$

where  $pa_k$  denotes a set of parents for the node  $x_k$ .

Each of the conditional distributions will typically have some parametric form. (e.g. product of Bernoullis in the noisy-OR case)

Important restriction: There must be **no directed cycles!** (i.e. graph is a DAG)

## Crucial property: easy sampling

Consider a joint distribution over K random variables  $p(x_1, x_2, ..., x_K)$ t factorizes as:

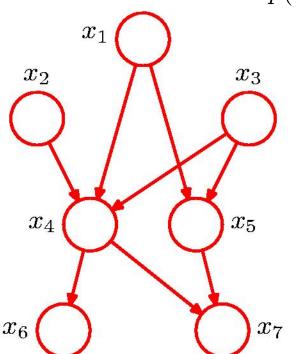

$$p(\mathbf{x}) = \prod_{k=1}^{N} p(x_k | \mathrm{pa}_k)$$
Suppose each of

Suppose each of the conditional distributions are easy to sample from. How do we sample from the joint?

Start at the top and sample in order.

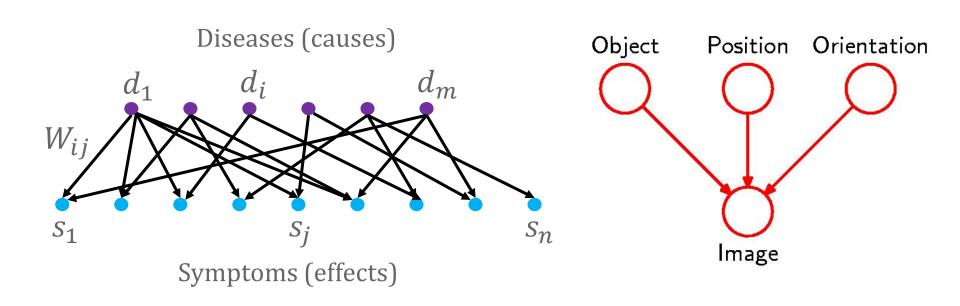

$$\hat{x}_1 \sim p(x_1)$$
 The parent variables are set to their sampled values  $\hat{x}_4 \sim p(x_4|\hat{x}_1,\hat{x}_2,\hat{x}_3)$   $\hat{x}_5 \sim p(x_5|\hat{x}_1,\hat{x}_3)$ 

To obtain a sample from the marginal distribution, e.g.  $p(x_2, x_5)$ , sample from the full joint distribution, retain  $\hat{x}_2, \hat{x}_5$ , discard the remaining values.

### The latent-variable paradigm

More often than not, we need to model part of the data that is **not observable**. We already saw examples of this:

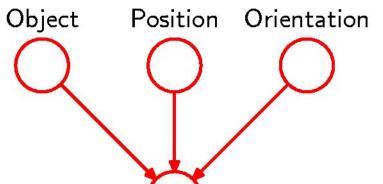

This is also a natural way to extract **features/representation**: the latent variables contain "meaningful" information.

## The latent-variable paradigm: deep learning

Higher-up nodes will typically represent latent (hidden) random variables.

The role of latent variables is to allow modeling a **complicated** distribution over observed variables **constructed** from **simpler** conditional distributions.

Latent-variable model of image

**I**mage

Object identity, position, and orientation have independent *prior probabilities*.

Image has probability distr that depends on object identity, position, and orientation (conditional distribution/likelihood).

$$P(Im, Ob, Po, Or) = P(Im|Ob, Po, Or)P(Ob)P(Po)P(Or)$$
Likelihood Prior

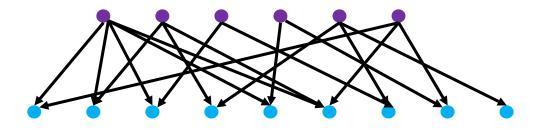

Likelihood and prior are modeled by parametric distribution whose parameters are fitted throughout training.

## Examples: single-layer latent-variable Bayesian networks

#### Simple, but powerful paradigm:

single-layer Bayesian networks, where top nodes are latent.

Latent variables Z

Observable variables X

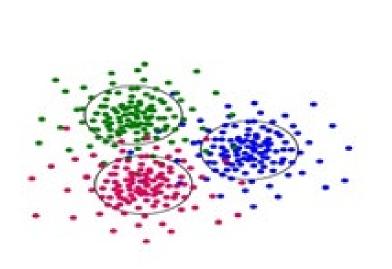

$$p_{\theta}(X,Z) = p_{\theta}(Z) p_{\theta}(X|Z)$$

### Example 1: Mixture distributions

**Mixture models:** observables = points; latent = clustering

To draw a sample (X,Z):

Sample Z from a categorial distr. on K components with parameters  $\{\pi_i\}$  Sample X from the corresponding component in the mixture.

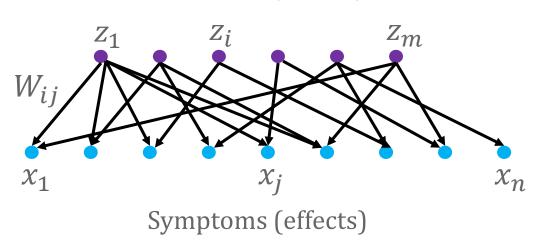

$$orall k:\pi_k\geqslant 0$$
  $\sum_{k=1}^K\pi_k=1$   $p(\mathbf{x})=\sum_{k=1}^K\pi_k\mathcal{N}(\mathbf{x}|oldsymbol{\mu}_k,oldsymbol{\Sigma}_k)$  Component Mixing coefficient

## Example 2: Noisy-OR networks

 $x_i, z_j \in \{0, 1\}$  $W_{ij} \ge 0$ 

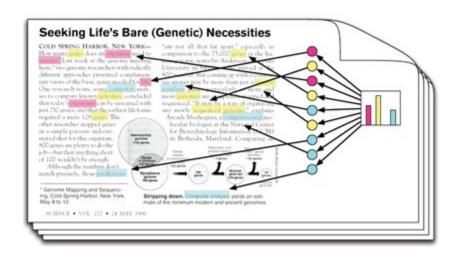

Diseases (causes)

Sample each  $z_i$  is on **independently** with prob.  $\rho$  When  $z_i$  is on, it **activates**  $x_j$  with probability  $1 - \exp(-W_{ij})$ . So  $x_j$  is **on** if one of  $z_i$ 's **activates**  $x_j$ 

## Example 3: Topic models (LDA)

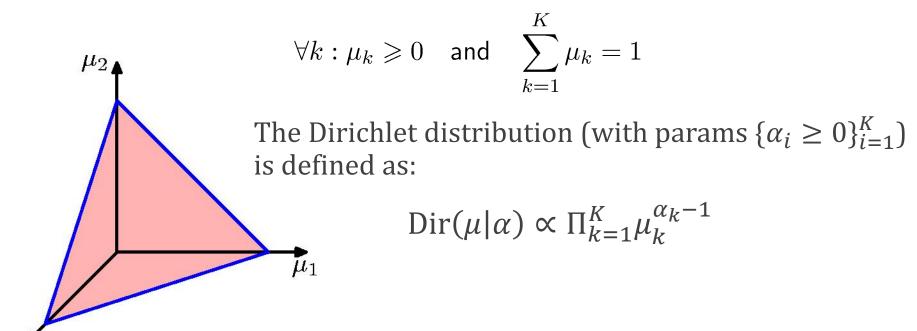

**Latent Dirichlet Allocation:** famous model for modeling topic structure of documents of text. (Blei, Ng, Jordan '03)

### Side-remark: Dirichlet Distribution

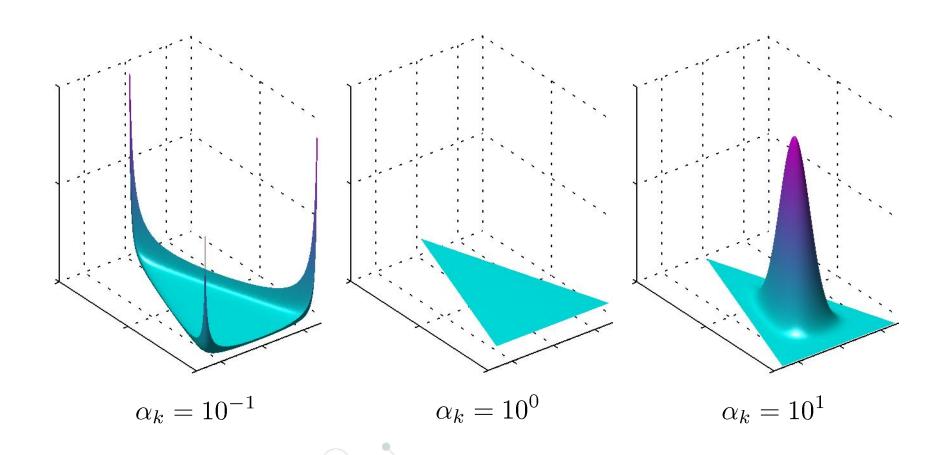

Consider a distribution over simplex, namely over points  $\{\mu_i\}_{i=1}^K$ 

 $\mu_3$ 

### Side-remark: Dirichlet Distribution

Plots of the Dirichlet distribution over three variables.

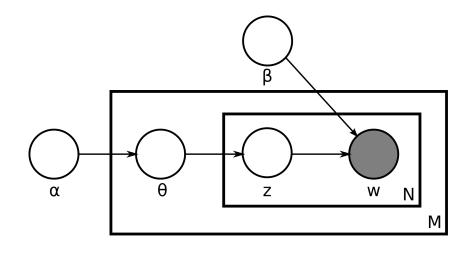

## Example 3: Topic models (LDA)

Defines a distribution over documents, involving K topics.

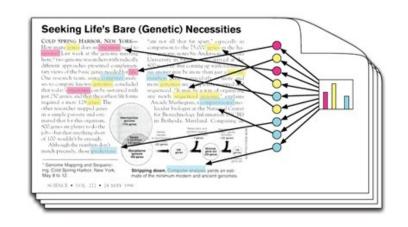

The **parameters** are:  $\{\alpha_i\}_{i=1}^K$  (Dirichlet parameters) and matrix  $\beta \in \mathbb{R}_+^{N \times K}$ , where N is the size of the vocabulary.

The columns of  $\beta$  satisfy  $\sum_{j=1}^{N} \beta_{ij} = 1$  (the distribution of words in a topic i)

#### To produce document:

- First, sample  $\theta \sim \text{Dir}(\cdot | \alpha)$ : this will be the topic proportion vector for the document.
- \* Each word in the document is generated in order, independently.
- To generate word i:
  - **Sample topic**  $z_i$  with categorical distribution with parameters  $\theta$
  - Sample word  $w_i$  with categorical distribution with parameters  $\beta_{z_i}$

## Example 3: Topic models (LDA)

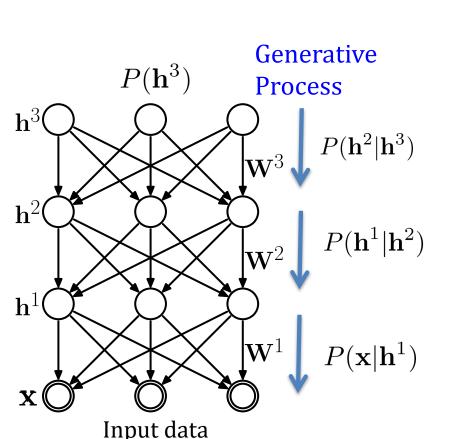

"Arts"	"Budgets"	"Children"	"Education"

THEATER	PROGRAMS	PERCENT	PRESIDENT
ACTRESS	GOVERNMENT	CARE	ELEMENTARY
LOVE	CONGRESS	LIFE	HAITI

The William Randolph Hearst Foundation will give \$1.25 million to Lincoln Center, Metropolitan Opera Co., New York Philharmonic and Juilliard School. "Our board felt that we had a real opportunity to make a mark on the future of the performing arts with these grants an act every bit as important as our traditional areas of support in health, medical research, education and the social services," Hearst Foundation President Randolph A. Hearst said Monday in announcing the grants. Lincoln Center's share will be \$200,000 for its new building, which will house young artists and provide new public facilities. The Metropolitan Opera Co. and New York Philharmonic will receive \$400,000 each. The Juilliard School, where music and the performing arts are taught, will get \$250,000. The Hearst Foundation, a leading supporter of the Lincoln Center Consolidated Corporate Fund, will make its usual annual \$100,000 donation, too.

## Example 4: Variational Autoencoder

Directed Bayesian network with Gaussian layers

$$p(\mathbf{x}|\boldsymbol{\theta}) = \sum_{\mathbf{h}^1, \dots, \mathbf{h}^L} p(\mathbf{h}^L|\boldsymbol{\theta}) p(\mathbf{h}^{L-1}|\mathbf{h}^L, \boldsymbol{\theta}) \cdots p(\mathbf{x}|\mathbf{h}^1, \boldsymbol{\theta})$$

Each term may denote a complicated nonlinear relationship

Layers are parametrized as:

$$p(\mathbf{h}^{L-1}|\mathbf{h}^{L}, \boldsymbol{\theta}) = \mathcal{N}(\mu_{\boldsymbol{\theta}}(\mathbf{h}^{L}), \Sigma_{\boldsymbol{\theta}}(\mathbf{h}^{L}))$$

Gaussians, means/covariances functions (e.g. neural net) of previous layer and model parameters  $\theta$ .

Easy to sample!

### Part II: variational methods

# How do you learn a latent-variable Bayesian network?

The most obvious strategy: maximum likelihood estimation

Given data  $x_1, x_2, ..., x_n$ , solve the optimization problem

$$\max_{\theta \in \Theta} \sum_{i=1}^{n} \log p_{\theta}(x_i)$$

How would you evaluate  $p_{\theta}(x_i)$ ?

Same partition function problem as in unnormalized models...

$$p_{\theta}(x) = \int_{h} p_{\theta}(h) p_{\theta}(x|h)$$
, e.g.  $\sum_{\text{Diseases}} P(\text{Diseases, Symptoms})$ 

Again, can be #P-hard to approximate.

### Another way to view the problem

Sampling from Bayesian networks is easy.

But: sampling/approximating the posterior distribution P(Z|X) is **hard**:

$$P(Diseases, Symptoms) = P(Diseases) P(Symptoms|Diseases)$$

Latent

Data

Simple, explicit

By Bayes rule,  $P(\text{Diseases}|\text{Symptoms}) \propto P(\text{Diseases},\text{Symptoms})$ 

Up to normalizing const, simple...

Complicated partition function:

 $\sum_{\text{Diseases}} P(\text{Diseases}, \text{Symptoms})$ 

*Gibbs variational principle*: Let p(z,x) be a joint distribution over latent variables and observables. Then,

$$p(z|x) = \underset{q(z|x): \text{distribution over } Z}{\operatorname{argmax}} \mathbb{E}_{q(z|x)} \log q(z|x) - \mathbb{E}_{q(z|x)} \log p(z,x)$$
$$-H(q(z|x)) - \mathbb{E}_{z \sim q} [\log p(z,x)]$$

Furthermore, for every q(z|x), we have

$$\log p(x) = -\left(-H(q(z|x)) - \mathbb{E}_{z \sim q}[\log p(z,x)]\right) + KL(q(z|x)) |p(z|x)|$$

# Variational methods for partition functions

*Gibbs variational principle*: Let p(z,x) be a joint distribution over latent variables and observables. Then,

$$p(z|x) = \underset{q(z|x): \text{distribution over } Z}{\operatorname{argmax}} \mathbb{E}_{q(z|x)} \log q(z|x) - \mathbb{E}_{q(z|x)} \log p(z,x)$$

In fact, for every q(z|x), we have

$$\log p(x) = KL(q(z|x)) \Big| p(z|x) \Big) - \Big( -H(q(z|x)) - \mathbb{E}_{z \sim q}[\log p(z,x)] \Big)$$

Why: 
$$0 \le KL(q(z|x)) | p(z|x) = \mathbb{E}_{q(z|x)} \log q(z|x) - \mathbb{E}_{q(z|x)} p(z|x)$$
$$= -H(q(z|x)) - \mathbb{E}_{q(z|x)} \log \frac{p(z,x)}{p(x)}$$
$$= -H(q(z|x)) - \mathbb{E}_{q(z|x)} \log p(z,x) + \log p(x)$$

Equality is attained if and only if KL(q(z|x)||p(z|x))=0 i. e. q(z|x)=p(z|x)

*Gibbs variational principle*: Let p(z, x) be a joint distribution over latent variables and observables. Then,

$$p(z|x) = \underset{q(z|x): \text{distribution over } Z}{\operatorname{argmax}} \mathbb{E}_{q(z|x)} \log q(z|x) - \mathbb{E}_{q(z|x)} \log p(z,x)$$

$$\log p(x) = -\left(-H(q(z|x)) - \mathbb{E}_{z \sim q}[\log p(z,x)]\right) + KL(q(z|x)) |p(z|x)|$$

Why is this useful?

(1) *Approximating posteriors*: Instead of finding the argmax over **all** distributions over Z, we can maximize over some **simpler** parametric family Q, i.e. we can solve

 $\max_{q(z|x)\in\mathcal{Q}} \mathbb{E}_{q(z|x)} \log q(z|x) - \mathbb{E}_{q(z|x)} \log p(z,x)$ 

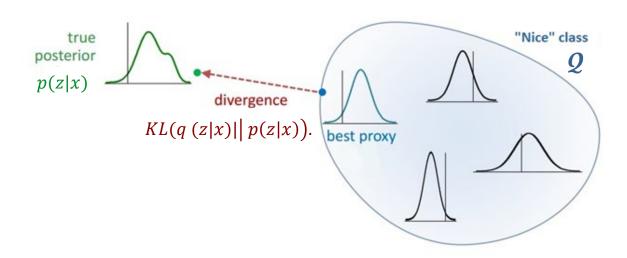

The argmax of the above distribution solves  $\min_{q(z|x) \in Q} KL(q(z|x)||p(z|x))$ .

In other words, we are finding the **projection** of p(z|x) onto Q.

*Gibbs variational principle*: Let p(z, x) be a joint distribution over latent variables and observables. Then,

$$p(z|x) = \underset{q(z|x): \text{distribution over } Z}{\operatorname{argmax}} \mathbb{E}_{q(z|x)} \log q(z|x) - \mathbb{E}_{q(z|x)} \log p(z,x)$$

$$\log p(x) = -\left(-H(q(z|x)) - \mathbb{E}_{z \sim q}[\log p(z,x)]\right) + KL(q(z|x)||p(z|x))$$

*Gibbs variational principle*: Let p(z, x) be a joint distribution over latent variables and observables. Then,

$$p(z|x) = \underset{q(z|x): \text{distribution over } Z}{\operatorname{argmax}} \mathbb{E}_{q(z|x)} \log q(z|x) - \mathbb{E}_{q(z|x)} \log p(z,x)$$

$$\log p(x) = -\left(-H(q(z|x)) - \mathbb{E}_{z \sim q}[p(z,x)]\right) + KL(q(z|x)||p(z|x))$$

Why is this useful?

(1) *Approximating posteriors*: Instead of finding the argmax over **all** distributions over Z, we can maximize over some **simpler** parametric family Q, i.e. we can solve

 $\max_{q(z|x) \in \mathcal{Q}} \mathbb{E}_{q(z|x)} \log q(z|x) - \mathbb{E}_{q(z|x)} \log p(z,x)$ 

There are several common families *Q* that are used for which the above optimization is solveable – we will see **mean-field** families and **neural-net** parametrized families.

*Gibbs variational principle*: Let p(z, x) be a joint distribution over latent variables and observables. Then,

$$p(z|x) = \underset{q(z|x): \text{distribution over } Z}{\operatorname{argmax}} \mathbb{E}_{q(z|x)} \log q(z|x) - \mathbb{E}_{q(z|x)} \log p(z,x)$$

$$\log p(x) = -\left(-H(q(z|x)) - \mathbb{E}_{z \sim q}[p(z,x)]\right) + KL(q(z|x)||p(z|x))$$

Why is this useful?

(2) *Approximate likelihood-based learning*: provides a lower bound on  $\log p(x)$  -- sometimes called the **ELBO (evidence lower bound)**, since

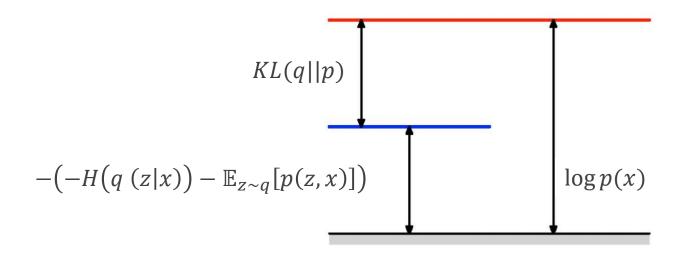

$$\log p(x) \ge \max_{q(z|x) \in Q} \mathbb{E}_{q(z|x)} \log q(z|x) - \mathbb{E}_{q(z|x)} \log p(z,x)$$

This will be useful for learning latent-variable directed models (stay tuned!).

*Gibbs variational principle*: Let p(z, x) be a joint distribution over latent variables and observables. Then,

$$p(z|x) = \underset{q(z|x): \text{distribution over } Z}{\operatorname{argmax}} \mathbb{E}_{q(z|x)} \log q(z|x) - \mathbb{E}_{q(z|x)} \log p(z,x)$$

$$\log p(x) = -\left(-H(q(z|x)) - \mathbb{E}_{z \sim q}[p(z,x)]\right) + KL(q(z|x)||p(z|x))$$

## Example: solving the mean-field relaxation via coordinate ascent

**Inspiration from physics**: consider the case where Q contains product distributions, that is, for every  $q(\cdot | x) \in Q$ :

$$q(z|x) = \prod_{i=1}^{d} q_i(z_i|x).$$

Consider updating a **single** coordinate of the mean-field distribution, that is keep  $q_{-i}$  ( $z_i|x$ ) fixed and optimize for  $q_i$  ( $z_i|x$ ). We have:

$$\min_{\boldsymbol{q}(\boldsymbol{Z}|\boldsymbol{X}) \in \mathcal{Q}} KL(q(\boldsymbol{z}|\boldsymbol{x})||p(\boldsymbol{z}|\boldsymbol{x})) = \min_{\boldsymbol{q}(\boldsymbol{Z}|\boldsymbol{X}) \in \mathcal{Q}} \mathbb{E}_{q(\boldsymbol{z}|\boldsymbol{x})} \log q(\boldsymbol{z}|\boldsymbol{x}) - \mathbb{E}_{q(\boldsymbol{z}|\boldsymbol{x})} \log p(\boldsymbol{z},\boldsymbol{x})$$

$$= \min_{\boldsymbol{q}(\boldsymbol{Z}|\boldsymbol{X}) \in \mathcal{Q}} \sum_{i} \mathbb{E}_{q_{i}(z_{i}|\boldsymbol{x})} \log q_{i}(z_{i}|\boldsymbol{x}) - \mathbb{E}_{q_{i}(z_{i}|\boldsymbol{x})} \left[ \mathbb{E}_{q_{-i}(\boldsymbol{z}_{-i}|\boldsymbol{x})} \log p(\boldsymbol{z}_{i}, \boldsymbol{z}_{-i}, \boldsymbol{x}) \right]$$

$$= \min_{\boldsymbol{q}(\boldsymbol{Z}|\boldsymbol{X}) \in \mathcal{Q}} \mathbb{E}_{q_{i}(z_{i}|\boldsymbol{x})} \log q_{i}(z_{i}|\boldsymbol{x}) - \mathbb{E}_{q_{i}(z_{i}|\boldsymbol{x})} [\log \tilde{p}(z_{i}, \boldsymbol{x})] + C$$

Renormalize to make it a distribution

## Example: solving the mean-field relaxation via coordinate ascent

**Inspiration from physics**: consider the case where Q contains product distributions, that is, for every  $q(\cdot | x) \in Q$ :

$$q(z|x) = \prod_{i=1}^d q_i(z_i|x).$$

Consider updating a **single** coordinate of the mean-field distribution, that is keep  $q_{-i}$  ( $z_i|x$ ) fixed, and optimize for  $q_i$  ( $z_i|x$ ). We have:

$$\min_{\boldsymbol{q}(\boldsymbol{z}|\boldsymbol{x}) \in \mathcal{Q}} KL(\boldsymbol{q}(\boldsymbol{z}|\boldsymbol{x})| \left| p(\boldsymbol{z}|\boldsymbol{x}) \right| = \min_{\boldsymbol{q}(\boldsymbol{z}|\boldsymbol{x}) \in \mathcal{Q}} \mathbb{E}_{q(\boldsymbol{z}|\boldsymbol{x})} \log q(\boldsymbol{z}|\boldsymbol{x}) - \mathbb{E}_{q(\boldsymbol{z}|\boldsymbol{x})} \log p(\boldsymbol{z},\boldsymbol{x})$$

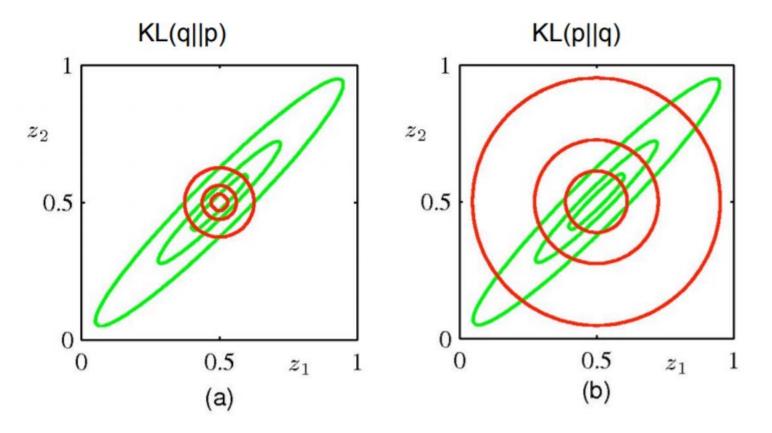

$$= \min_{q(\boldsymbol{z}|\boldsymbol{x}) \in \mathcal{Q}} KL(q_i(z_i|\boldsymbol{x})||\tilde{p}(z_i,\boldsymbol{x})) + C$$

Optimum is 
$$q_i(z_i|x) = \tilde{p}(z_i,x)$$

$$= \frac{\mathbb{E}_{q_{-i}(Z_{-i}|x)} \log p(z_i, z_{-i}, x)}{\int_{Z_i} \mathbb{E}_{q_{-i}(Z_{-i}|x)} \log p(z_i, z_{-i}, x)}$$

Coordinate ascent: iterate above updates!

### A tale of two KL divergences

Approximation is too compact.

Approximation is too spread.

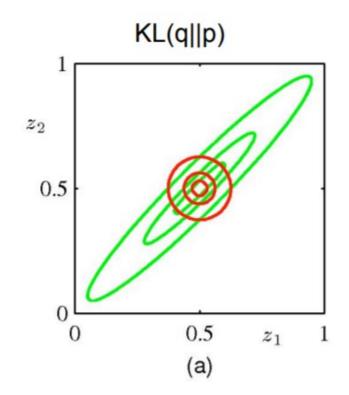

## The "variational" KL divergence

$$\mathrm{KL}(q||p) = -\int q(\mathbf{Z}) \ln \frac{p(\mathbf{Z})}{q(\mathbf{Z})} d\mathbf{Z}.$$

There is a large positive contribution to the KL divergence from regions of Z space in which:

- p(Z) is near zero
- unless q(Z) is also close to zero.

Minimizing KL(q||p) leads to distributions q(Z) that avoid regions in which p(Z) is small.

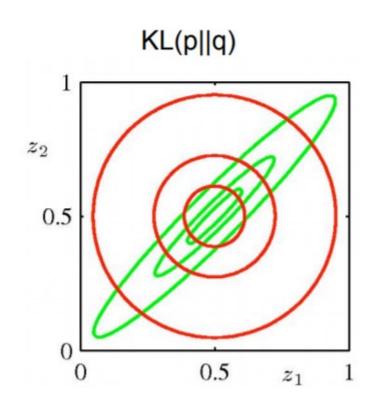

## The "maximum likelihood" KL divergence

$$\mathrm{KL}(p||q) = -\int p(\mathbf{Z}) \ln \frac{q(\mathbf{Z})}{p(\mathbf{Z})} \mathrm{d}\mathbf{Z}.$$

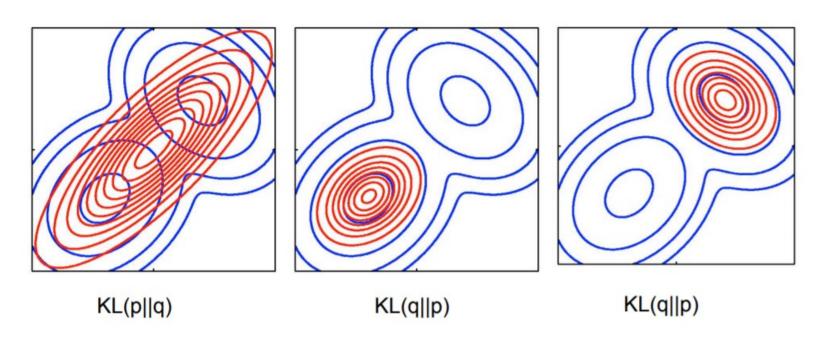

There is a large positive contribution to the KL divergence from regions of Z space in which:

- q(Z) is near zero,
- unless p(Z) is also close to zero.

Minimizing KL(p||q) leads to distributions q(Z) that are nonzero in regions where p(Z) is nonzero.

## What happens when distribution class for Q is not rich enough?

Blue contours show bimodal distribution, red contours single Gaussian distribution that best approximates it.

KL(q||p) will tend to find a single mode, whereas KL(p||q) will average across all of the modes.

# Learning single-layer latent-variable Bayesian networks using variational methods

## Rewriting the maximum likelihood objective

Recall maximum likelihood objective:

Given data  $x_1, x_2, ..., x_n$ , solve the optimization problem

$$\max_{\theta \in \Theta} \sum_{i=1}^{n} \log p(x_i)$$

Latent variables: we will use the Gibbs variational principle again!

$$\log_{\theta} p(x) = \max_{q(z|x): \text{ distribution over } \mathcal{Z}} H(q(z|x)) + \mathbb{E}_{q(z|x)}[\log p_{\theta}(x,z)]$$

Hence, MLE objective can be written as double maximization:

$$\max_{\theta \in \Theta} \max_{\{q_i(z|x_i)\}} \sum_{i=1}^n H(q_i(z|x_i)) + \mathbb{E}_{q_i(z|x_i)}[\log p_{\theta}(x_i, z)]$$

## Expectation-maximization/variational inference

The canonical algorithm for learning a single-layer latent-variable Bayesian network is an iterative algorithm as follows.

Consider the max-likelihood objective, rewritten as in the previous slide:

$$\max_{\theta \in \Theta} \max_{\{q_i(z|x_i) \in \mathbf{Q}\}} \sum_{i=1}^n H(q_i(z|x_i)) + \mathbb{E}_{q_i(z|x_i)}[\log p_{\theta}(x_i, z)]$$

Algorithm maintains iterates  $\theta^t$ ,  $\{q_i^t(z|x_i)\}$ , and updates them iteratively

(1) Expectation (E)-step:

Keep  $\theta^t$  fixed, set  $\{q_i^{t+1}(z|x_i) \in Q\}$ , s.t. they maximize the objective above.

(2) Maximization (M)-step:

Keep  $\{q_i^t(z|x_i)\}$  fixed, set  $\theta^{t+1}$  s.t. it maximizes the objective above.

Clearly, every step cannot make the objective worse!

Does \*not\* mean it converges to global optimum – could, e.g. get stuck in a local minimum.

## Expectation-maximization/variational inference

The canonical algorithm for learning a single-layer latent-variable Bayesian network is an iterative algorithm as follows.

Consider the max-likelihood objective, rewritten as in the previous slide:  $\max_{\theta \in \Theta} \max_{q_i(z|x_i)} \sum_{i=1}^n H(q_i(z|x_i)) + \mathbb{E}_{q_i(z|x_i)}[\log p_\theta(x_i,z)]$ 

Algorithm maintains iterates  $\theta^t$ ,  $q_i^t(z|x_i)$ , and updates them iteratively

#### (1) Expectation step:

Keep  $\theta^t$  and set  $q_i^{t+1}(z|x_i)$ , s.t. they maximize the objective above.

If the class is infinitely rich, the optimum is  $q_i^{t+1}(z|x_i) = p_{\theta^t}(z|x_i)$ 

This is called **expectation-maximization (EM)**. If class is not infinitely rich, it's called **variational inference**.

## Example

#### Mixture of spherical Gaussians

Consider a mixture of K Gaussians with unknown means  $p = \sum_{i=1}^{K} \frac{1}{K} \mathcal{N}(\mu_i, I_d)$ 

Let's try to calculate the E and M steps.

**E-step**: the optimal  $q_i^{t+1}(z|x_i)$  is  $p_{\theta^t}(z|x_i)$ . Can we calculate this?

By Bayes rule, 
$$p_{\theta^t}(z = k|x_i) \propto p(x_i|z = k) \propto e^{-\left||x_i - \mu_k^t|\right|^2}$$

Writing out the normalizing constant, we have

$$p_{\theta^t}(z = k|x_i) = \frac{e^{-||x_i - \mu_k^t||^2}}{\sum_{k'} e^{-||x_i - \mu_{k'}^t||^2}}$$

"Soft" version of assigning point to nearest cluster

## Example

#### Mixture of spherical Gaussians

Consider a mixture of K Gaussians with unknown means  $p = \sum_{i=1}^{K} \frac{1}{K} \mathcal{N}(\mu_i, I_d)$ 

Let's try to calculate the E and M steps.

**M-step**: given a quess  $q_i^t(z|x_i)$  , we can rewrite the maximization for  $\theta$  as:

$$\max_{\theta \in \Theta} \sum_{i=1}^{n} H(q_i^t(z|x_i)) + \mathbb{E}_{q_i^t(z|x_i)}[\log p_{\theta}(x_i, z)]$$

$$= \mathbb{E}_{q_i^t(z|x_i)}[\log p_{\theta}(x|z)]$$

$$= \mathbb{E}_{q_i^t(z|x_i)}[\log p_{\theta}(x|z)]$$

$$\mathbb{E}_{q_i^t(z|x_i)}[\log p_{\theta}(x|z)]$$

## Example

#### Mixture of spherical Gaussians

Consider a mixture of K Gaussians with unknown means  $p = \sum_{i=1}^{K} \frac{1}{\nu} \mathcal{N}(\mu_i, I_d)$ 

Let's try to calculate the E and M steps.

**M-step**: given a quess  $q_i^t(z|x_i)$ , we can rewrite the maximization for  $\theta$  as:

$$\max_{\theta} \mathbb{E}_{q_i^t(z|x_i)}[\log p_{\theta}(x|z)] = \max_{\theta} -\sum_{i=1}^n \sum_{k=1}^K q_i^t(z=k|x_i)||x_i - \mu_k||^2$$

Setting the derivative wrt to  $\mu_k$  to 0, we have:

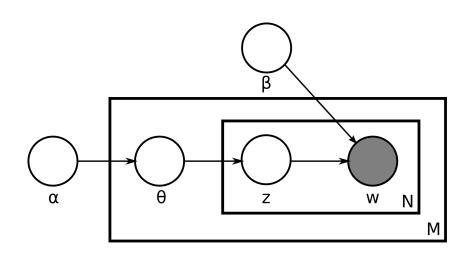

$$\mu_k^{t+1} = \sum_{i=1}^n \frac{e^{-\left||x_i - \mu_k^t|\right|^2}}{\sum_{k'} e^{-\left||x_i - \mu_{k'}^t|\right|^2}} \underbrace{x_i}$$
 Average points, weighing nearby points more

## Examples

#### 2: Latent Dirichlet Allocation

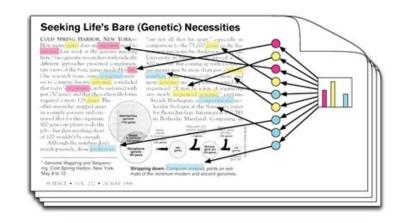

The **parameters** are:  $\{\alpha_i\}_{i=1}^K$  (Dirichlet parameters) and matrix  $\beta \in \mathbb{R}_+^{N \times K}$ , where N is the size of the vocabulary.

The columns of  $\beta$  satisfy  $\sum_{j=1}^{N} \beta_{ij} = 1$  (the distribution of words in a topic i)

#### To produce document:

- First, sample  $\theta \sim \text{Dir}(\cdot | \alpha)$ : this will be the topic proportion vector for the document.
- Each word in the document is generated in order, independently.
- ❖ To generate word i:
  - **Sample topic**  $z_i$  with categorical distribution with parameters  $\theta$
  - Sample word  $w_i$  with categorical distribution with parameters  $\beta_{z_i}$

## Examples

The E-step cannot be done in closed form:

$$\begin{split} p(\vec{\theta}_{1:D}, z_{1:D,1:N}, \vec{\beta}_{1:K} \mid w_{1:D,1:N}, \alpha, \eta) &= \\ \frac{p(\vec{\theta}_{1:D}, \vec{z}_{1:D}, \vec{\beta}_{1:K} \mid \vec{w}_{1:D}, \alpha, \eta)}{\int_{\vec{\beta}_{1:K}} \int_{\vec{\theta}_{1:D}} \sum_{\vec{z}} p(\vec{\theta}_{1:D}, \vec{z}_{1:D}, \vec{\beta}_{1:K} \mid \vec{w}_{1:D}, \alpha, \eta)} \end{split}$$

(In fact, can be shown to be #P-hard to perform in the worst case.)

The variational family to approximate the posterior is commonly chosen to be a mean-field family:

$$q(\vec{\theta}_{1:D}, z_{1:D,1:N}, \vec{\beta}_{1:K}) = \prod_{k=1}^{K} q(\vec{\beta}_k \mid \vec{\lambda}_k) \prod_{d=1}^{D} \left( q(\vec{\theta}_{dd} \mid \vec{\gamma}_d) \prod_{n=1}^{N} q(z_{d,n} \mid \vec{\phi}_{d,n}) \right)$$

- Probability of topic z given document d:  $q(\theta_d \mid \gamma_d)$  Each document has its own Dirichlet prior  $\gamma_d$
- -Probability of word w given topic z:  $q(\beta_z \mid \lambda_z)$  Each topic has its own Dirichlet prior  $\lambda_z$
- Probability of topic assignment to word  $w_{d,n}$ :  $q(z_{d,n} \mid \varphi_{d,n})$  Each word position word[d][n] has its own prior  $\varphi_{d,n}$

## Examples

$$q(\vec{\theta}_{1:D}, z_{1:D,1:N}, \vec{\beta}_{1:K}) = \prod_{k=1}^{K} q(\vec{\beta}_k \mid \vec{\lambda}_k) \prod_{d=1}^{D} \left( q(\vec{\theta}_{dd} \mid \vec{\gamma}_d) \prod_{n=1}^{N} q(z_{d,n} \mid \vec{\phi}_{d,n}) \right)$$

- Probability of topic z given document d:  $q(\theta_d \mid \gamma_d)$  Each document has its own Dirichlet prior  $\gamma_d$
- -Probability of word w given topic z:  $q(\beta_z \mid \lambda_z)$  Each topic has its own Dirichlet prior  $\lambda_z$
- -Probability of topic assignment to word  $w_{d,n}$ :  $q(z_{d,n} \mid \varphi_{d,n})$  Each word position word[d][n] has its own prior  $\varphi_{d,n}$

#### One iteration of mean field variational inference for LDA

(1) For each topic k and term v:

(8) 
$$\lambda_{k,v}^{(t+1)} = \eta + \sum_{d=1}^{D} \sum_{n=1}^{N} 1(w_{d,n} = v) \phi_{n,k}^{(t)}.$$

- (2) For each document *d*:
  - (a) Update  $\gamma_d$ :

(9) 
$$\gamma_{d,k}^{(t+1)} = \alpha_k + \sum_{n=1}^N \phi_{d,n,k}^{(t)}.$$

(b) For each word n, update  $\vec{\phi}_{d,n}$ :

(10) 
$$\phi_{d,n,k}^{(t+1)} \propto \exp\left\{\Psi(\gamma_{d,k}^{(t+1)}) + \Psi(\lambda_{k,w_n}^{(t+1)}) - \Psi(\sum_{v=1}^{V} \lambda_{k,v}^{(t+1)})\right\},\,$$

where  $\Psi$  is the digamma function, the first derivative of the  $\log \Gamma$  function.

Parameter updates:

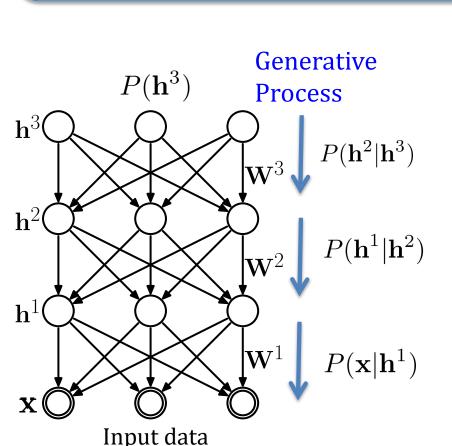

$$\beta_{ij} \propto \sum_{d=1}^{M} \sum_{n=1}^{N_d} \phi_{dni} w_{dn}^j.$$

## Learning variational autoencoders using variational methods

### Variational autoencoders

Directed Bayesian network with Gaussian layers

$$p(\mathbf{x}|\boldsymbol{\theta}) = \sum_{\mathbf{h}^1, \dots, \mathbf{h}^L} p(\mathbf{h}^L|\boldsymbol{\theta}) p(\mathbf{h}^{L-1}|\mathbf{h}^L, \boldsymbol{\theta}) \cdots p(\mathbf{x}|\mathbf{h}^1, \boldsymbol{\theta})$$

Each term may denote a complicated nonlinear relationship

Typically, directed layers are parametrized as:

$$p(\mathbf{h}^{L-1}|\mathbf{h}^{L}, \mathbf{\theta}) = \mathcal{N}(\mu_{\mathbf{\theta}}(\mathbf{h}^{L}), \Sigma_{\mathbf{\theta}}(\mathbf{h}^{L}))$$

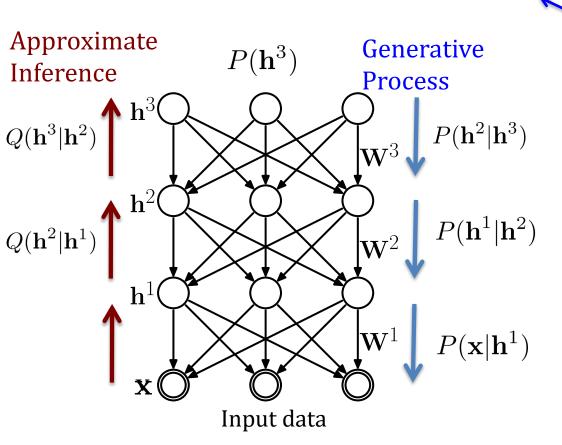

Gaussians, means/covariances functions (e.g. one-layer neural net) of previous layer and model parameters  $\theta$ .

Easy to sample!

## Approximate posterior family

The posterior family is defined in terms of an analogous factorization:

$$q(\mathbf{h}|\mathbf{x},\boldsymbol{\theta}) = q(\mathbf{h}^{1}|\mathbf{x},\boldsymbol{\theta})q(\mathbf{h}^{2}|\mathbf{h}^{1},\boldsymbol{\theta}) \dots q(\mathbf{h}^{L}|\mathbf{h}^{L-1},\boldsymbol{\theta})$$

Each term may denote a complicated nonlinear relationship

Typically, directed layers are parametrized as:

$$q(\mathbf{h}^{l}|\mathbf{h}^{l-1},\boldsymbol{\theta})$$

$$= \mathcal{N}(\mu_{\boldsymbol{\theta}}(\mathbf{h}^{l-1}), \Sigma_{\boldsymbol{\theta}}(\mathbf{h}^{l-1}))$$

Means/covariances fns (e.g. one-layer neural net) of previous layer and parameters  $\boldsymbol{\theta}$ .

Max-likelihood can be written as:

$$\max_{\theta \in \Theta} \max_{\left\{q_{\theta}(h^{L}|x)\right\}} \sum_{x} \mathbb{E}_{q_{\theta}(h^{L}|x)} \log \frac{p_{\theta}(x, h^{L})}{q_{\theta}(h^{L}|x)}$$

We want to be able to take gradients in  $\theta$ 

**The problem**: the expectation is with respect to  $q_{\theta}(h^L|x)$ , which depends on the variables we are taking a derivative with respect to.

**Observation**: a derivative of the type  $\nabla_{\theta} \mathbb{E}_p f(\theta)$  is easy to approximate if p does not depend on  $\theta$ :

$$\nabla_{\theta} \mathbb{E}_p f(\theta) = \mathbb{E}_p \nabla_{\theta} f(\theta) \qquad \theta_i \text{: iid samples from p}$$
 Exchange only works if 
$$\approx \frac{1}{N} \sum_i \nabla_{\theta_i} f(\theta_i)$$
 p doesn't dep on  $\theta$ 

Max-likelihood can be written as:

$$\max_{\theta \in \Theta} \max_{\left\{q_{\theta}(h^{L}|x)\right\}} \sum_{x} \mathbb{E}_{q_{\theta}(h^{L}|x)} \log \frac{p_{\theta}(x, h^{L})}{q_{\theta}(h^{L}|x)}$$

As usual: we need to be able to take gradients in  $\theta$ 

**Remark**: there is a common Monte Carlo estimator of  $\nabla_{\theta} \mathbb{E}_{p(\theta)} f(\theta)$  as well but it typically has high variance:

$$\nabla_{\theta} \mathbb{E}_{p(\theta)} f(\theta) = \int \nabla_{\theta} f(\theta) \, p(\theta) d\theta + \int f(\theta) \, \nabla_{\theta} p(\theta) d\theta$$

$$= \int \nabla_{\theta} f(\theta) p(\theta) d\theta + \int f(\theta) \frac{p(\theta)}{p(\theta)} \nabla_{\theta} p(\theta) d\theta$$

$$= \int \nabla_{\theta} f(\theta) p(\theta) d\theta + \int f(\theta) \nabla_{\theta} \log p(\theta) p(\theta) d\theta$$

$$= \mathbb{E}_{p(\theta)} [\nabla_{\theta} f(\theta) + f(\theta) \nabla_{\theta} \log p(\theta)]$$
 This term typically is high var.,

Max-likelihood can be written as:

$$\max_{\theta \in \Theta} \max_{\left\{q_{\theta}(h^{L}|x)\right\}} \sum_{x} \mathbb{E}_{q_{\theta}(h^{L}|x)} \log \frac{p_{\theta}(x, h^{L})}{q_{\theta}(h^{L}|x)}$$

As usual: we need to be able to take gradients in  $\theta$ 

**The solution**: write the expectation  $\mathbb{E}_{q_{\theta}(h^L|x)} \log \frac{p_{\theta}(x,h^L)}{q_{\theta}(h^L|x)}$  as an expectation over a distribution not dependent on  $\theta$ .

Kingma-Welling '13: reparametrization trick!

*Main idea:* a sample from  $\mathbf{y} \sim \mathcal{N}(\boldsymbol{\mu}, \boldsymbol{\Sigma})$  can be generated as follows Sample  $\mathbf{x} \sim \mathcal{N}(0, I)$ .

Output  $y = \mu + \Sigma^{1/2} x$ .

Max-likelihood can be written as:

$$\max_{\theta \in \Theta} \max_{\left\{q_{\theta}(h^{L}|x)\right\}} \sum_{x} \mathbb{E}_{q_{\theta}(h^{L}|x)} \log \frac{p_{\theta}(x, h^{L})}{q_{\theta}(h^{L}|x)}$$

As usual: we need to be able to take gradients in  $\theta$ 

Recall that 
$$q(\mathbf{h}|\mathbf{x}, \boldsymbol{\theta}) = q(\mathbf{h}^1|\mathbf{x}, \boldsymbol{\theta})q(\mathbf{h}^2|\mathbf{h}^1, \boldsymbol{\theta}) \dots q(\mathbf{h}^L|\mathbf{h}^{L-1}, \boldsymbol{\theta})$$

where 
$$q(\mathbf{h}^l | \mathbf{h}^{l-1}, \boldsymbol{\theta}) = \mathcal{N}(\mu_{\boldsymbol{\theta}}(\mathbf{h}^{l-1}), \Sigma_{\boldsymbol{\theta}}(\mathbf{h}^{l-1}))$$

To produce a sample from  $q(h|x,\theta)$ , sample iid standard Gaussians  $\epsilon_1, \epsilon_2, ..., \epsilon_L$ . Set

$$\mathbf{h}^{\ell}\left(\boldsymbol{\epsilon}^{\ell},\mathbf{h}^{\ell-1},oldsymbol{ heta}
ight) = \mathbf{\Sigma}(\mathbf{h}^{\ell-1},oldsymbol{ heta})^{1/2}oldsymbol{\epsilon}^{\ell} + oldsymbol{\mu}(\mathbf{h}^{\ell-1},oldsymbol{ heta})$$

## Using the reparametrization trick

Max-likelihood can be written as:

$$\max_{\theta \in \Theta} \max_{\{q_{\theta}(h)\}} \sum_{x} \mathbb{E}_{q_{\theta}(h|x)} \log \frac{p_{\theta}(x,h)}{q_{\theta}(h|x)}$$

We can hence write the gradient wrt to  $\theta$ :

$$\nabla_{\boldsymbol{\theta}} \mathbb{E}_{\mathbf{h} \sim q(\mathbf{h}|\mathbf{x}, \boldsymbol{\theta})} \left[ \log \frac{p(\mathbf{x}, \mathbf{h}|\boldsymbol{\theta})}{q(\mathbf{h}|\mathbf{x}, \boldsymbol{\theta})} \right]$$

$$= \nabla_{\boldsymbol{\theta}} \mathbb{E}_{\boldsymbol{\epsilon}^1, \dots, \boldsymbol{\epsilon}^L \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I})} \left[ \log \frac{p(\mathbf{x}, \mathbf{h}(\boldsymbol{\epsilon}, \mathbf{x}, \boldsymbol{\theta}) | \boldsymbol{\theta})}{q(\mathbf{h}(\boldsymbol{\epsilon}, \mathbf{x}, \boldsymbol{\theta}) | \mathbf{x}, \boldsymbol{\theta})} \right]$$

$$= \mathbb{E}_{\boldsymbol{\epsilon}^1, \dots, \boldsymbol{\epsilon}^L \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I})} \left[ \nabla_{\boldsymbol{\theta}} \log \frac{p(\mathbf{x}, \mathbf{h}(\boldsymbol{\epsilon}, \mathbf{x}, \boldsymbol{\theta}) | \boldsymbol{\theta})}{q(\mathbf{h}(\boldsymbol{\epsilon}, \mathbf{x}, \boldsymbol{\theta}) | \mathbf{x}, \boldsymbol{\theta})} \right]$$

## Using the reparametrization trick

Max-likelihood can be written as:

$$\max_{\theta \in \Theta} \max_{\{q_{\theta}(h)\}} \sum_{x} \mathbb{E}_{q_{\theta}(h|x)} \log \frac{p_{\theta}(x,h)}{q_{\theta}(h|x)}$$

We can hence write the gradient wrt to  $\theta$ :

$$\nabla_{\boldsymbol{\theta}} \mathbb{E}_{\mathbf{h} \sim q(\mathbf{h}|\mathbf{x},\boldsymbol{\theta})} \left[ \log \frac{p(\mathbf{x}, \mathbf{h}|\boldsymbol{\theta})}{q(\mathbf{h}|\mathbf{x}, \boldsymbol{\theta})} \right] = \nabla_{\boldsymbol{\theta}} \mathbb{E}_{\boldsymbol{\epsilon}^{1}, \dots, \boldsymbol{\epsilon}^{L} \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I})} \left[ \log \frac{p(\mathbf{x}, \mathbf{h}(\boldsymbol{\epsilon}, \mathbf{x}, \boldsymbol{\theta})|\boldsymbol{\theta})}{q(\mathbf{h}(\boldsymbol{\epsilon}, \mathbf{x}, \boldsymbol{\theta})|\mathbf{x}, \boldsymbol{\theta})} \right]$$

$$= \mathbb{E}_{\boldsymbol{\epsilon}^1, \dots, \boldsymbol{\epsilon}^L \sim \mathcal{N}(\mathbf{0}, \boldsymbol{I})} \left[ \nabla_{\boldsymbol{\theta}} \log \frac{p(\mathbf{x}, \mathbf{h}(\boldsymbol{\epsilon}, \mathbf{x}, \boldsymbol{\theta}) | \boldsymbol{\theta})}{q(\mathbf{h}(\boldsymbol{\epsilon}, \mathbf{x}, \boldsymbol{\theta}) | \mathbf{x}, \boldsymbol{\theta})} \right]$$

We can approximate the expectation by an empirical average as before.

For **fixed**  $\epsilon_1$ ,  $\epsilon_2$ , ...,  $\epsilon_L$ : log p and log q are easy to take gradients of via backpropagating.

It's common to have **diagonal covariance mxs** for training efficiency.
